Excerpt from Reconstruction From Zero-Crossings in Scale-Space A useful representation of signal data, besides being a complete and stable transformation of the information, should make explicit useful features in the data. In computer vision, the one-parameter family of images obtained from the Laplacian of a Gaussian-filtered version of the image, parameterized by the width of the Gaussian, has proven to be a useful data structure for the extraction of feature data. In particular, the zero-crossings of this so-called scale-space data are associated with edges, and were proposed by Marr and others as the basis of a representation of the image data. The question arises as to whether the representation is complete and stable. We survey some of the results and studies related to these questions, and survey several papers that attempt reconstructions based on this or related representations. We then formulate a new method for the reconstruction from zero-crossings in scale-space, based on minimizing equation error, and present results showing that the reconstruction is possible, but can be unstable. We further show that the method applies when gradient data along the zero-crossings is...
